An improved integrated circuit and a related system apparatus and method. The integrated circuit includes a plurality of logic area or user logic areas; and an actively switchable network capable of selectively connecting at least one logic area with another logic area. In particular, the plurality of logic areas include an array of logic-gates or logic-blocks or custom logic which form functional blocks. The integrated circuit can provide a chip-architecture where the functional blocks are specific hardware functional blocks, hardware functional blocks that are parameterized, and/or programmable functional blocks including programmable processors. Also, the functional blocks can act as objects requesting and providing services to other objects on the actively switchable network so that, when a functional block is a programmable processor, the functional block optionally implements objects, with the programmable processor making one, some or all objects thereof visible to other objects connected to the actively switchable network.
